Failure modes, effects, and criticality analysis (FMECA) is a methodology to identify and analyze:

- ❑ All potential failure modes of the various parts of a system
- ❑ The effects these failures may have on the system
- ❑ How to avoid the failures, and/or mitigate the effects of the failures on the system

FMECA is a technique used to *identify, prioritize, and eliminate* potential failures from the system, design or process before they reach the customer

– Omdahl (1988)

FMECA is a technique to “resolve potential problems in a system before they occur”

– SEMATECH (1992)

Initially, the FMECA was called FMEA (Failure modes and effects analysis). The C in FMECA indicates that the criticality (or severity) of the various failure effects are considered and ranked. Today, FMEA is often used as a synonym for FMECA. The distinction between the two terms has become blurred.

Conclusions

- ❑ FMECA was one of the first systematic techniques for failure analysis
- ❑ FMECA was developed by the U.S. Military. The first guideline was Military Procedure MIL-P-1629 “Procedures for performing a failure mode, effects and criticality analysis” dated November 9, 1949
- ❑ FMECA is the most widely used reliability analysis technique in the initial stages of product/system development
- ❑ FMECA is usually performed during the conceptual and initial design phases of the system in order to assure that all potential failure modes have been considered and the proper provisions have been made to eliminate these failures

Conclusions

- ❑ Assist in selecting design alternatives with high reliability and high safety potential during the early design phases
- ❑ Ensure that all conceivable failure modes and their effects on operational success of the system have been considered
- ❑ List potential failures and identify the severity of their effects
- ❑ Develop early criteria for test planning and requirements for test equipment
- ❑ Provide historical documentation for future reference to aid in analysis of field failures and consideration of design changes
- ❑ Provide a basis for maintenance planning
- ❑ Provide a basis for quantitative reliability and availability analyses.

Conclusions

- How can each part conceivably fail?
- What mechanisms might produce these modes of failure?
- What could the effects be if the failures did occur?
- Is the failure in the safe or unsafe direction?
- How is the failure detected?
- What inherent provisions are provided in the design to compensate for the failure?

# When to perform an FMECA

The FMECA should be initiated as early in the design process, where we are able to have the greatest impact on the equipment reliability. The locked-in cost versus the total cost of a product is illustrated in the figure:

- ❑ *Design FMECA* is carried out to eliminate failures during equipment design, taking into account all types of failures during the whole life-span of the equipment
- ❑ *Process FMECA* is focused on problems stemming from how the equipment is manufactured, maintained or operated
- ❑ *System FMECA* looks for potential problems and bottlenecks in larger processes, such as entire production lines

### □ Bottom-up approach

- ❖ The bottom-up approach is used when a system concept has been decided. Each component on the lowest level of indenture is studied one-by-one. The bottom-up approach is also called *hardware* approach. The analysis is *complete* since all components are considered.

### □ Top-down approach

- ❖ The top-down approach is mainly used in an early design phase before the whole system structure is decided. The analysis is usually function oriented. The analysis starts with the main system functions - and how these may fail. Functional failures with significant effects are usually prioritized in the analysis. The analysis will not necessarily be complete. The top-down approach may also be used on an existing system to focus on problem areas.

1. Define the system to be analyzed
  - (a) System boundaries (which parts should be included and which should not)
  - (b) Main system missions and functions (incl. functional requirements)
  - (c) Operational and environmental conditions to be considered  
Note: Interfaces that cross the design boundary should be included in the analysis
2. Collect available information that describes the system to be analyzed; including drawings, specifications, schematics, component lists, interface information, functional descriptions, and so on
3. Collect information about previous and similar designs from internal and external sources; including FRACAS data, interviews with design personnel, operations and maintenance personnel, component suppliers, and so on

1. Divide the system into manageable units - typically functional elements. To what level of detail we should break down the system will depend on the objective of the analysis. It is often desirable to illustrate the structure by a hierarchical tree diagram:

## System structure analysis - (2)

In some applications it may be beneficial to illustrate the system by a functional block diagram (FBD) as illustrated in the following figure.

Conclusions

The analysis should be carried out on an as high level in the system hierarchy as possible. If unacceptable consequences are discovered on this level of resolution, then the particular element (subsystem, sub-subsystem, or component) should be divided into further detail to identify failure modes and failure causes on a lower level.

To start on a too low level will give a complete analysis, but may at the same time be a waste of efforts and money.

# Preparation of FMECA worksheets

A suitable FMECA worksheet for the analysis has to be decided. In many cases the client (customer) will have requirements to the worksheet format - for example to fit into his maintenance management system. A sample FMECA worksheet covering the most relevant columns is given below.

Conclusions

For each system element (subsystem, component) the analyst must consider all the functions of the elements in all its operational modes, and ask if any failure of the element may result in any unacceptable system effect. If the answer is NO, then no further analysis of that element is necessary. If the answer is YES, then the element must be examined further.

We will now discuss the various columns in the FMECA worksheet on the previous slide.

1. In the first column a unique reference to an element (subsystem or component) is given. It may be a reference to an id. in a specific drawing, a so-called tag number, or the name of the element.
2. The functions of the element are listed. It is important to list all functions. A checklist may be useful to secure that all functions are covered.

3. The various operational modes for the element are listed. Example of operational modes are: idle, standby, and running. Operational modes for an airplane include, for example, taxi, take-off, climb, cruise, descent, approach, flare-out, and roll. In applications where it is not relevant to distinguish between operational modes, this column may be omitted.
4. For each function and operational mode of an element the potential failure modes have to be identified and listed. Note that a failure mode should be defined as a nonfulfillment of the functional requirements of the functions specified in column 2.

5. The failure modes identified in column 4 are studied one-by-one. The failure mechanisms (e.g., corrosion, erosion, fatigue) that may produce or contribute to a failure mode are identified and listed. Other possible causes of the failure mode should also be listed. It may be beneficial to use a checklist to secure that all relevant causes are considered. Other relevant sources include: FMD-97 “Failure Mode/Mechanism Distributions” published by RAC, and OREDA (for offshore equipment)
6. The various possibilities for detection of the identified failure modes are listed. These may involve diagnostic testing, different alarms, proof testing, human perception, and the like. Some failure modes are *evident*, other are *hidden*. The failure mode “fail to start” of a pump with operational mode “standby” is an example of a hidden failure.

## Preparation of FMECA worksheets - (4)

In some applications an extra column is added to rank the likelihood that the failure will be detected before the system reaches the end-user/customer. The following detection ranking may be used:

Rank	Description
1-2	Very high probability that the defect will be detected. Verification and/or controls will almost certainly detect the existence of a deficiency or defect.
3-4	High probability that the defect will be detected. Verification and/or controls have a good chance of detecting the existence of a deficiency/defect.
5-7	Moderate probability that the defect will be detected. Verification and/or controls are likely to detect the existence of a deficiency or defect.
8-9	Low probability that the defect will be detected. Verification and/or control not likely to detect the existence of a deficiency or defect.
10	Very low (or zero) probability that the defect will be detected. Verification and/or controls will not or cannot detect the existence of a deficiency/defect.

7. The effects each failure mode may have on other components in the same subsystem and on the subsystem as such (*local effects*) are listed.
8. The effects each failure mode may have on the system (*global effects*) are listed. The resulting operational status of the system after the failure may also be recorded, that is, whether the system is functioning or not, or is switched over to another operational mode. In some applications it may be beneficial to consider each category of effects separately, like: safety effects, environmental effects, production availability effects, economic effects, and so on.

In some applications it may be relevant to include separate columns in the worksheet for *Effects on safety*, *Effects on availability*, etc.

9. Failure rates for each failure mode are listed. In many cases it is more suitable to classify the failure rate in rather broad classes. An example of such a classification is:

1	Very unlikely	Once per 1000 years or more seldom
2	Remote	Once per 100 years
3	Occasional	Once per 10 years
4	Probable	Once per year
5	Frequent	Once per month or more often

## Preparation of FMECA worksheets - (8)

10. The severity of a failure mode is the worst potential (but realistic) effect of the failure considered on the system level (the *global effects*). The following severity classes for health and safety effects are sometimes adopted:

Rank	Severity class	Description
10	Catastrophic	Failure results in major injury or death of personnel.
7-9	Critical	Failure results in minor injury to personnel, personnel exposure to harmful chemicals or radiation, or fire or a release of chemical to the environment.
4-6	Major	Failure results in a low level of exposure to personnel, or activates facility alarm system.
1-3	Minor	Failure results in minor system damage but does not cause injury to personnel, allow any kind of exposure to operational or service personnel or allow any release of chemicals into the environment

The risk associated to failure mode is a function of the frequency of the failure mode and the potential end effects (severity) of the failure mode. The risk may be illustrated in a so-called risk matrix.

Conclusions

An alternative to the risk matrix is to use the ranking of:

- O = the rank of the occurrence of the failure mode
- S = the rank of the severity of the failure mode
- D = the rank of the likelihood the the failure will be detected before the system reaches the end-user/customer.

All ranks are given on a scale from 1 to 10. The *risk priority number* (RPN) is defined as

$$RPN = S \times O \times D$$

The smaller the RPN the better – and – the larger the worse.

Conclusions

A design FMECA should be initiated by the design engineer, and the system/process FMECA by the systems engineer. The following personnel may participate in reviewing the FMECA (the participation will depend on type of equipment, application, and available resources):

- Project manager
- Design engineer (hardware/software/systems)
- Test engineer
- Reliability engineer
- Quality engineer
- Maintenance engineer
- Field service engineer
- Manufacturing/process engineer
- Safety engineer

## Review objectives

The review team studies the FMECA worksheets and the risk matrices and/or the risk priority numbers (RPN). The main objectives are:

1. To decide whether or not the system is acceptable
2. To identify feasible improvements of the system to reduce the risk. This may be achieved by:
  - (a) Reducing the likelihood of occurrence of the failure
  - (b) Reducing the effects of the failure
  - (c) Increasing the likelihood that the failure is detected before the system reaches the end-user.

If improvements are decided, the FMECA worksheets have to be revised and the RPN should be updated.

Problem solving tools like brainstorming, flow charts, Pareto charts and nominal group technique may be useful during the review process.

# RPN reduction

The risk reduction related to a corrective action may be compared by comparing the RPN for the initial and revised concept, respectively. A simple example is given in the following table.

	<b>Occurrence O</b>	<b>Severity S</b>	<b>Detection D</b>	<b>RPN</b>
<b>Initial</b>	7	8	5	280
<b>Revised</b>	5	8	4	160

**Pros and cons**

## Pros:

- ❑ FMECA is a very structured and reliable method for evaluating hardware and systems
- ❑ The concept and application are easy to learn, even by a novice
- ❑ The approach makes evaluating even complex systems easy to do

## Cons:

- ❑ The FMECA process may be tedious, time-consuming (and expensive)
- ❑ The approach is not suitable for multiple failures
- ❑ It is too easy to forget human errors in the analysis
